# CyberShield CLI

Cybersecurity Incident Tracker

**Prajakta Roy Arpa**

## 1. About the Project

CyberShield CLI is a terminal-based cybersecurity incident tracker built in Python. It lets users log, manage, and report on security incidents directly from the command line. The interface is powered by the rich library for clean, colour-coded output. All data is saved to a JSON file so it persists between sessions.

## 2. Features

### Create Incident

This method adds a new incident by asking the user for a title, attack type, and severity level. A date and unique ID is assigned automatically. Input is validated and empty fields and invalid severity values are rejected.

### List Incidents

With this method all saved incidents are in a formatted table with columns for ID, Title, Attack Type, Severity, Status, and Date. Shows a friendly message if no incidents are existing yet.

### Update Incident Status

This method allows the user to change the status of an existing incident by entering its ID. Valid status options are Open, Resolved, and Closed. Invalid IDs and non-numeric input are handled automatically.

### Delete Incident

This method removes an incident by ID. The user is asked to confirm before deletion so records are not accidentally lost.

### Search Incidents

This method filters the incident list by keyword, severity level. The results are displayed in the same formatted table. If nothing matches a clear message is shown.

### Severity Report

This method generates a summary table showing how many incidents exist at each severity level along with a total count. It is useful for a quick overview of the current security situation.

### Auto-Save & Persistence

All the data is automatically saved to incidents.json after every create, update, or delete action. On startup the program loads existing data from the file, so nothing gets lost between sessions.

## 3. Setup & Run Commands

### Step 1 :  Creating a virtual environment

```
python -m venv .venv
```

### Step 2 : Activating the virtual environment

```
.venv\Scripts\activate
```

### Step 3 : Installing required packages

```
pip install -r requirements.txt
pip install rich
```

### Step 4 : Run the application

```
python main.py
```

### Step 5 : Freeze dependencies

```
pip freeze > requirements.txt
```

## 4. Screenshots
